Motivation

Purpose of multifractal analysis : Introduce and study classification and model selection parameters for data (functions, measures, distributions, signals, images), which are based on global and local regularity

Motivation

Purpose of multifractal analysis : Introduce and study classification and model selection parameters for data (functions, measures, distributions, signals, images), which are based on global and local regularity

A key problem along the 19th century was to determine if a continuous function on \mathbb{R} necessarily has points of differentiability

A first negative answer was obtained by B. Bolzano in 1830 but was unnoticed

A second counterexample due to K. Weierstrass settled the issue in 1872

Weierstrass functions

$$W_H(x) = \sum_{j=0}^{+\infty} 2^{-Hj} \cos(2^j x)$$

 $0 < H < 1$

ヘロト ヘポト ヘヨト ヘヨト

Weierstrass result was sharpened using a continuous scale of pointwise regularity indices

Pointwise regularity

Definition :

Let $f : \mathbb{R}^d \to \mathbb{R}$ be a locally bounded function and $x_0 \in \mathbb{R}^d$; $f \in C^{\alpha}(x_0)$ if there exist C > 0 and a polynomial P such that, for $|x - x_0|$ small enough,

$$|f(x) - P(x - x_0)| \leq C|x - x_0|^{\alpha}$$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Pointwise regularity

Definition :

Let $f : \mathbb{R}^d \to \mathbb{R}$ be a locally bounded function and $x_0 \in \mathbb{R}^d$; $f \in C^{\alpha}(x_0)$ if there exist C > 0 and a polynomial P such that, for $|x - x_0|$ small enough,

$$|f(x) - P(x - x_0)| \le C|x - x_0|^{\alpha}$$

The Hölder exponent of f at x_0 is

$$h_f(x_0) = \sup\{\alpha: f \in C^{\alpha}(x_0)\}$$

Theorem : (Hardy, 1916) The Hölder exponent of W_H is constant and equal to H (W_H is a mono-Hölder function)

Riemann's nondifferentiable function :

$$\mathcal{R}_2(x) = \sum_{n=1}^{\infty} \frac{\sin(n^2 x)}{n^2}$$

Riemann's nondifferentiable function :

$$\mathcal{R}_2(x) = \sum_{n=1}^{\infty} \frac{\sin(n^2 x)}{n^2}$$

(日) (日) (日) (日) (日) (日) (日)

The cubic Riemann function : $\mathcal{R}_3(x) = \sum_{n=1}^{\infty} \frac{\sin(n^3 x)}{n^3}$

Riemann's nondifferentiable function :

$$\mathcal{R}_2(x) = \sum_{n=1}^{\infty} \frac{\sin(n^2 x)}{n^2}$$

The cubic Riemann function : $\mathcal{R}_3(x) = \sum_{x \in A} \frac{1}{x^2}$

$$=\sum_{n=1}^{\infty}\frac{\sin(n^3x)}{n^3}$$

Minkowski's "question mark" function : ?(x) : [0, 1] \rightarrow [0, 1] If $x = [0; a_1, \dots a_n, \dots]$ then ?(x) = $2 \sum \frac{(-1)^{n+1}}{2^{a_1 + \dots + a_n}}$

(日) (日) (日) (日) (日) (日) (日)

Riemann's nondifferentiable function :

$$\mathcal{R}_2(x) = \sum_{n=1}^{\infty} \frac{\sin(n^2 x)}{n^2}$$

The cubic Riemann function : $\mathcal{R}_3(x) = \sum_{n=1}^{\infty} \frac{\sin(n^3 x)}{n^3}$

C. Hermite : "Je me détourne avec effroi et horreur de cette plaie lamentable des fonctions qui n'ont pas de dérivée"

H. Poincaré called such functions "monsters"

Brownian motion

Economists (L. Bachelier) and physicists (A. Einstein) put into light the central role played by Brownian motion in modeling

Definition:

Brownian motion is the unique continuous process with independent and stationary increments

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Theorem : (Paley, Wiener, Zygmund, 1933) With probability 1, The Hölder exponent of Brownian motion is constant and equal to 1/2 (Brownian motion has mono-Hölder sample paths)

In 1931, S. Banach proved that a "generic" continuous function on \mathbb{R} is nowhere differentiable (in the sense of Baire categories)

Nowhere differentiable functions

Starting with the example of the surface of colloïds, and the coast of Brittany, J. Perrin, in his book, "Les atomes" published in 1913, insists that such examples, far from being exceptional, supply the right models for natural phenomena

Functional interpretation : Lipschitz spaces

$$\int |f(x+\delta) - f(x)|^{p} dx \sim |\delta|^{\zeta_{f}(p)}$$

Definition : Let $p \in [1, \infty)$; $f \in Lip(s, L^p(\mathbb{R}^d))$ if

 $\exists C > 0, \ \forall \delta > 0, \qquad \parallel f(\cdot + \delta) - f(\cdot) \parallel_{p} \leq C \cdot |\delta|^{s}$

$$\exists C > 0, \ \forall \delta > 0, \qquad \int |f(x + \delta) - f(x)|^p dx \leq C \cdot |\delta|^{ps}$$

 $\forall p \geq 1, \qquad \zeta_f(p) = p \cdot \sup \{s : f \in Lip(s, L^p)\}$

One can replace the spaces $Lip(s, L^p(\mathbb{R}^d))$ by Sobolev spaces

$$L^{p,s} = \{f \in L^p : \ (-\Delta)^{s/2} f \in L^p\}$$

The scaling function yields a regularity index in the L^p norm

One-variable wavelet basis

A wavelet basis on \mathbb{R} is generated by a smooth, well localized, oscillating function ψ such that the

 $\psi(2^{j}x - k), \quad j, k \in \mathbb{Z}$ form an orthogonal basis of $L^{2}(\mathbb{R})$

where

$$c_{j,k} = 2^j \int f(x) \ \psi(2^j x - k) \ dx$$

Daubechies Wavelet

Notations for wavelets on $\ensuremath{\mathbb{R}}$

Dyadic intervals

$$\lambda = \left[\frac{k}{2^j}, \frac{k+1}{2^j}\right)$$

Wavelets

$$\psi_{\lambda}(\mathbf{x}) = \psi(\mathbf{2}^{j}\mathbf{x} - \mathbf{k})$$

Wavelet coefficients

$$c_{\lambda} = 2^j \int_{\mathbb{R}} f(x) \psi(2^j x - k) dx$$

Dyadic intervals at scale *j*

$$\Lambda_j = \{\lambda : |\lambda| = \mathbf{2}^{-j}\}$$

Wavelet expansion of f

$$f(x) = \sum_{j} \sum_{\lambda \in \Lambda_{j}} c_{\lambda} \psi_{\lambda}(x)$$

Wavelets in 2 variables

In 2D, the wavelets used are tensor products :

$$\psi^1(\mathbf{x},\mathbf{y}) = \psi(\mathbf{x})\varphi(\mathbf{y})$$

$$\psi^2(\mathbf{x},\mathbf{y}) = \varphi(\mathbf{x})\psi(\mathbf{y})$$

$$\psi^3(\mathbf{x},\mathbf{y}) = \psi(\mathbf{x})\psi(\mathbf{y})$$

The wavelet scaling function

Let $f : \mathbb{R}^d \to \mathbb{R}$; its wavelet scaling function is defined $\forall p > 0$ by

$$2^{-dj}\sum_{\lambda\in\Lambda_{j}}|c_{\lambda}|^{p}\sim2^{-\zeta_{f}(p)j}\quad\text{i.e.}\quad\zeta_{f}(p)=\liminf_{j\rightarrow+\infty}\frac{\log\left(2^{-dj}\sum_{\lambda\in\Lambda_{j}}|c_{\lambda}|^{p}\right)}{\log(2^{-j})}$$

The wavelet scaling function

Let $f : \mathbb{R}^d \to \mathbb{R}$; its wavelet scaling function is defined $\forall p > 0$ by

$$2^{-dj} \sum_{\lambda \in \Lambda_j} |c_{\lambda}|^p \sim 2^{-\zeta_f(p)j} \quad \text{i.e.} \quad \zeta_f(p) = \liminf_{j \to +\infty} \frac{\log\left(2^{-dj} \sum_{\lambda \in \Lambda_j} |c_{\lambda}|^p\right)}{\log(2^{-j})}$$

1

\

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Besov spaces : Let p>0 ; $f\in B^{s,\infty}_{\rho}(\mathbb{R}^d)$ if

$$\exists m{C}, orall j: \qquad 2^{-dj} \sum_{\lambda \in m{\Lambda}_j} |m{c}_\lambda|^p \leq m{C} \cdot 2^{-spj}$$

The wavelet scaling function

Let $f : \mathbb{R}^d \to \mathbb{R}$; its wavelet scaling function is defined $\forall p > 0$ by

$$2^{-dj} \sum_{\lambda \in \Lambda_j} |c_{\lambda}|^p \sim 2^{-\zeta_f(p)j} \quad \text{i.e.} \quad \zeta_f(p) = \liminf_{j \to +\infty} \frac{\log\left(2^{-dj} \sum_{\lambda \in \Lambda_j} |c_{\lambda}|^p\right)}{\log(2^{-j})}$$

1

1

Besov spaces : Let p > 0 ; $f \in B^{s,\infty}_{\rho}(\mathbb{R}^d)$ if

$$\exists C, \forall j: \qquad 2^{-dj} \sum_{\lambda \in \Lambda_j} |c_{\lambda}|^p \le C \cdot 2^{-spj}$$
$$\frac{\log\left(2^{-dj} \sum_{\lambda \in \Lambda_j} |c_{\lambda}|^p\right)}{\log(2^{-j})} = p \cdot \sup\left\{s: f \in B_p^{s,\infty}(\mathbb{R}^d)\right\}$$

Embeddings between Lipschitz and Besov spaces imply that, when $p \ge 1$, the wavelet scaling function coincides with Kolmogorov's scaling function

The role of the wavelet scaling function

$$orall oldsymbol{
ho} > oldsymbol{0}, \qquad \quad \zeta_f(oldsymbol{
ho}) = oldsymbol{
ho} \cdot \sup \ \left\{ oldsymbol{s} : f \in B^{oldsymbol{s},\infty}_{oldsymbol{
ho}}
ight\}$$

◆□ > ◆□ > ◆ 三 > ◆ 三 > ● ○ ○ ○ ○

The role of the wavelet scaling function

$$\forall p > 0, \qquad \zeta_f(p) = p \cdot \sup \{s : f \in B_p^{s,\infty}\}$$

The wavelet scaling function is independent of the (smooth enough) wavelet basis chosen

It is defined by regression on log-log plots

The role of the wavelet scaling function

$$\forall p > 0, \qquad \zeta_f(p) = p \cdot \sup \{s : f \in B_p^{s,\infty}\}$$

The wavelet scaling function is independent of the (smooth enough) wavelet basis chosen

It is defined by regression on log-log plots

• If
$$\zeta_f(1) > 1$$
, then $f \in BV$

- If *f* is a measure, then $\zeta_f(1) \ge 0$
- If $\zeta_f(1) > 0$, f then belongs to L^1
- If $\zeta_f(2) > 0$, then $f \in L^2$

Motivations :

Limitations

Classification only based on the wavelet scaling function or on the uniform Hölder exponent proved insufficient in several occurrences (turbulence, data mining, ...)

Limitations

Classification only based on the wavelet scaling function or on the uniform Hölder exponent proved insufficient in several occurrences (turbulence, data mining, ...)

Further developments were based on seminal ideas introduced by U. Frisch and G. Parisi, and paved the way to the construction of a new scaling function

Giorgio Parisi

Uriel Frisch

・ロト・日本・モト・モー ショー ショー

Multifractal spectrum (Parisi and Frisch, 1985)

The isohölder sets of *f* are the sets

$$E_H = \{x_0 : h_f(x_0) = H\}$$

Multifractal spectrum (Parisi and Frisch, 1985)

The isohölder sets of *f* are the sets

$$E_H = \{x_0 : h_f(x_0) = H\}$$

Let *f* be a locally bounded function. The multifractal spectrum of *f* is

 $D_f(H) = \dim (E_H)$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

where dim stands for the Hausdorff dimension (by convention, dim $(\emptyset) = -\infty$)

Multifractal spectrum (Parisi and Frisch, 1985)

The isohölder sets of f are the sets

$$E_H = \{x_0 : h_f(x_0) = H\}$$

Let *f* be a locally bounded function. The multifractal spectrum of *f* is

 $D_f(H) = \dim (E_H)$

where dim stands for the Hausdorff dimension (by convention, dim $(\emptyset) = -\infty$)

Parisi and Frisch's fundamental idea was that the nonlinearity of the scaling function reflects the presence of a whole range of fractal sets E_H , and that the scaling function yields information on the "sizes" of these sets

Two results showed that multifractal analysis does not only concern "strange examples" :

I : Probabilistic result :

Definition : A Lévy process is a stochastic process with independent and stationary increments, i.e. :

 $X_{t+s} - X_t$ is independent of the $\{X_u, u \leq t\}$ and has the same law as X_s

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

 $X_{t+s} - X_t$ is independent of the $\{X_u, u \le t\}$ and has the same law as X_s

Theorem : (S.J.) "Most" Lévy processes have multifractal sample paths, with a linear multifractal spectrum :

$$D_f(H) = \left\{egin{array}{cc} RH & ext{if} & H < 1/R \ -\infty & ext{else.} \end{array}
ight.$$

In each case, the sets E_H are everywhere dense

The numerical determination of the Hölder exponent is hopeless

II : Generic results :

Definition : Let *E* be a metric Banach space. A Borel set $A \subset E$ is Haar null if there exists a compactly supported probability measure μ on *E* such that

 $\forall x \in E, \qquad \mu(A+x) = 0$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

A set is prevalent if its complement is Haar null

If a property holds on a prevalent set, it is said to hold almost everywhere

II : Generic results :

Definition : Let *E* be a metric Banach space. A Borel set $A \subset E$ is Haar null if there exists a compactly supported probability measure μ on *E* such that

 $\forall x \in E, \qquad \mu(A+x) = 0$

A set is prevalent if its complement is Haar null

If a property holds on a prevalent set, it is said to hold almost everywhere

Theorem : (A. Fraysse and S. J.) Let s > d/p; then quasi-every and almost every function *f* of $L^{p,s}(\mathbb{R}^d)$ is multifractal, and its spectrum is given by

$$\mathcal{D}_f(\mathcal{H}) = \left\{egin{array}{cc} \mathcal{p}(\mathcal{H}-s) + d & ext{if} \quad \mathcal{H} \in \left[s - rac{d}{p}, s
ight] \ -\infty & ext{else} \end{array}
ight.$$

Wavelet leaders

Let λ be a dyadic cube ; 3 λ denotes the cube of same center and three times wider

Let f be a locally bounded function; the wavelet leaders of f are

 $d_\lambda = \sup_{\lambda' \subset \mathfrak{Z}\lambda} |c_{\lambda'}|$

Computation of 2D wavelet leaders

Wavelet leaders allow to estimate the pointwise Hölder exponent

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ─ □ ─ の < @

$\begin{array}{l} \text{Wavelet scaling function} \\ 2^{-\textit{dj}} \sum_{\lambda \in \Lambda_{j}} |\textit{c}_{\lambda}|^{\textit{p}} \sim 2^{-\zeta_{f}(\textit{p})j} \end{array}$

Leader scaling function $2^{-dj} \sum_{\lambda \in \Lambda_i} |d_\lambda|^p \sim 2^{-\eta_f(p)j}$

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

$$\frac{\text{Wavelet scaling function}}{2^{-dj}\sum_{\lambda\in\Lambda_j}|c_\lambda|^{\rho}\sim 2^{-\zeta_f(\rho)j}}$$

Leader scaling function
$$2^{-dj} \sum_{\lambda \in \Lambda_j} |d_{\lambda}|^p \sim 2^{-\eta_f(p)j}$$

Oscillation spaces : Let p > 0; $f \in O_p^s(\mathbb{R}^d)$ if

$$\exists m{C}, orall j: \qquad 2^{-dj} \sum_{\lambda \in m{\Lambda}_j} |m{d}_\lambda|^p \leq m{C} \cdot 2^{-spj}$$

Similar to Wiener Amalgam Spaces (H. Feichtinger, K. Gröchenig)

$\frac{\text{Wavelet scaling function}}{2^{-dj}\sum_{\lambda\in\Lambda_j}|c_\lambda|^{\rho}\sim 2^{-\zeta_f(\rho)j}}$

Leader scaling function
$$2^{-dj} \sum_{\lambda \in \Lambda_j} |d_{\lambda}|^p \sim 2^{-\eta_f(p)j}$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Oscillation spaces : Let p > 0; $f \in O_p^s(\mathbb{R}^d)$ if

$$\exists m{C}, orall j: \qquad 2^{-dj} \sum_{\lambda \in \Lambda_j} |m{d}_\lambda|^p \leq m{C} \cdot 2^{-spj}$$

Similar to Wiener Amalgam Spaces (H. Feichtinger, K. Gröchenig)

$$\eta_f(p) = \liminf_{j \to +\infty} \frac{\log\left(2^{-dj}\sum |d_\lambda|^p\right)}{\log(2^{-j})} = p \cdot \sup\left\{s: f \in O_p^s(\mathbb{R}^d)\right\}$$

$$\begin{array}{l} \text{Wavelet scaling function} \\ 2^{-\textit{dj}} \sum_{\lambda \in \Lambda_{j}} |\textit{c}_{\lambda}|^{p} \sim 2^{-\zeta_{f}(\textit{p})j} \end{array}$$

Leader scaling function
$$2^{-dj} \sum_{\lambda \in \Lambda_j} |d_\lambda|^p \sim 2^{-\eta_f(p)j}$$

Oscillation spaces : Let p > 0; $f \in O_p^s(\mathbb{R}^d)$ if

$$\exists m{C}, orall j: \qquad 2^{-dj} \sum_{\lambda \in \Lambda_j} |m{d}_\lambda|^p \leq m{C} \cdot 2^{-spj}$$

Similar to Wiener Amalgam Spaces (H. Feichtinger, K. Gröchenig)

$$\eta_f(p) = \liminf_{j \to +\infty} \;\; \frac{\log\left(2^{-dj}\sum |d_\lambda|^p\right)}{\log(2^{-j})} = p \cdot \sup\left\{s: \;\; f \in O_p^s(\mathbb{R}^d)\right\}$$

Advantages :

- ▶ It is "well defined" for all $p \in \mathbb{R}$
- For *p* large enough, $\zeta_f(p) = \eta_f(p)$
- If ψⁱ ∈ S(ℝ^d), then ∀p ∈ ℝ, η_f(p) is independent of the wavelet basis
- ▶ η_f is invariant under "smooth perturbations" of f_{f_1}

Multifractal formalism

Since η_f is a concave function, there is no loss of information in rather considering its Legendre transform :

The Legendre Spectrum of f is

$$L_f(H) = \inf_{p \in \mathbb{R}} \left(d + Hp - \eta_f(p) \right)$$

Theorem : Let $D_f(H)$ denote the Hausdorff dimension of the set of points where $h_f(x) = H$. If $f \in C^{\varepsilon}(\mathbb{R}^d)$ for an $\varepsilon > 0$ then

$$\forall H \in \mathbb{R}, \qquad D_f(H) \leq \inf_{p \in \mathbb{R}} (d + Hp - \eta_f(p))$$

Multifractal formalism

Since η_f is a concave function, there is no loss of information in rather considering its Legendre transform :

The Legendre Spectrum of f is

$$L_f(H) = \inf_{p \in \mathbb{R}} \left(d + Hp - \eta_f(p) \right)$$

Theorem : Let $D_f(H)$ denote the Hausdorff dimension of the set of points where $h_f(x) = H$. If $f \in C^{\varepsilon}(\mathbb{R}^d)$ for an $\varepsilon > 0$ then

$$\forall H \in \mathbb{R}, \qquad D_f(H) \leq \inf_{p \in \mathbb{R}} (d + Hp - \eta_f(p))$$

The multifractal formalism is satisfied when equality holds

Open problem : Find "reasonably weak" general hypotheses implying the validity of the multifractal formalism
